

The scale up of TB/HIV collaborative activities  
in Asia-Pacific

# **TB/HIV Operational Research: Needs and Recent Advances**

**Khun Kim Eam, MD, MPH**

**Focal point for TB/HIV Collaboration,  
National Center for TB Control, CENAT**

# Operational Research: Definition

“Operational research is concerned with the day to day operations of programs. It is intended to provide managers, administrators, and policy-makers with the information that they need to improve service delivery activities and plan future ones. It seeks practical solutions to problem situations and viable alternatives to unsatisfactory operating methods.”

# Operational Research should:

- Address country-specific TB/HIV control issues
- Be conducted rapidly, with involvement from programme managers
- Lead to specific recommended interventions, including changes in national policy and national strategies

# Examples of Operational Research

## Questions for TB/HIV in Asia

- In HIV-infected patients diagnosed with TB, how do you reduce mortality?
- **What is the best way to screen for and diagnose TB in people with HIV?**
- Which TB infection control measures are most effective/cost-effective?
- What is the yield of contact-tracing among patients with pulmonary TB for TB case-finding? HIV case-finding?
- What is the cost-effectiveness of new diagnostic tests?

# **Need for intensified TB case finding among people with HIV**

- **Case-fatality rate for HIV-infected TB patients high (up to 25-50% during TB treatment)**
- **About half of deaths occur within 2 months**
- **Early diagnosis should decrease case-fatality**
- **Improve safety of ART initiation**
- **Improve uptake of IPT**
- **WHO recommendation**

# **Difficulty of TB screening in HIV-infected persons**

- **HIV-infected TB patients often lack classic TB symptoms**
- **Up to 30% of HIV-infected TB patients with pulmonary TB have a normal chest radiograph**
- **Sputum smears may be negative in 50% or more**
- **Currently, no internationally accepted, evidence-based approach to screening**

# Improving the Diagnosis of TB in HIV-infected Persons in SE Asia

- Objectives are to:
  - Develop an evidence-based clinical algorithm with high sensitivity to rule-out TB in HIV-infected persons
  - Develop an algorithm with high specificity to diagnose TB in HIV-infected persons
- Algorithm based on all patients, i.e. no assumptions about importance of cough or other symptoms
- Enroll broad cross-section of HIV-infected persons from multiple settings
- Use a sensitive combination of microbiological tests as the gold-standard

# Enrollment Sites & Sample Size

- Total planned enrollment: 2,050 across 3 countries
  - 600 in one site in Bangkok, Thailand
  - 1,000 in four sites in Cambodia
  - 450 in three sites in Ho Chi Minh City, Vietnam

## Thailand

Bangkok

## Cambodia

Phnom Penh

Battambang

Sereysophon

Mongkul Borei

## Vietnam

Ho Chi Minh City

# Study procedures

- Informed consent
- Questionnaire administered by doctor/nurse
- Patient examined by doctor
- Chest radiograph
- Lab tests: Blood count, CD4
- Microbiology
  - Culture and smear of 3 sputum, 1 urine, 1 stool, and 1 blood specimen
  - Lymph node aspirate cx if enlarged peripheral node
- Optional tests (by site): TST, HIV viral load

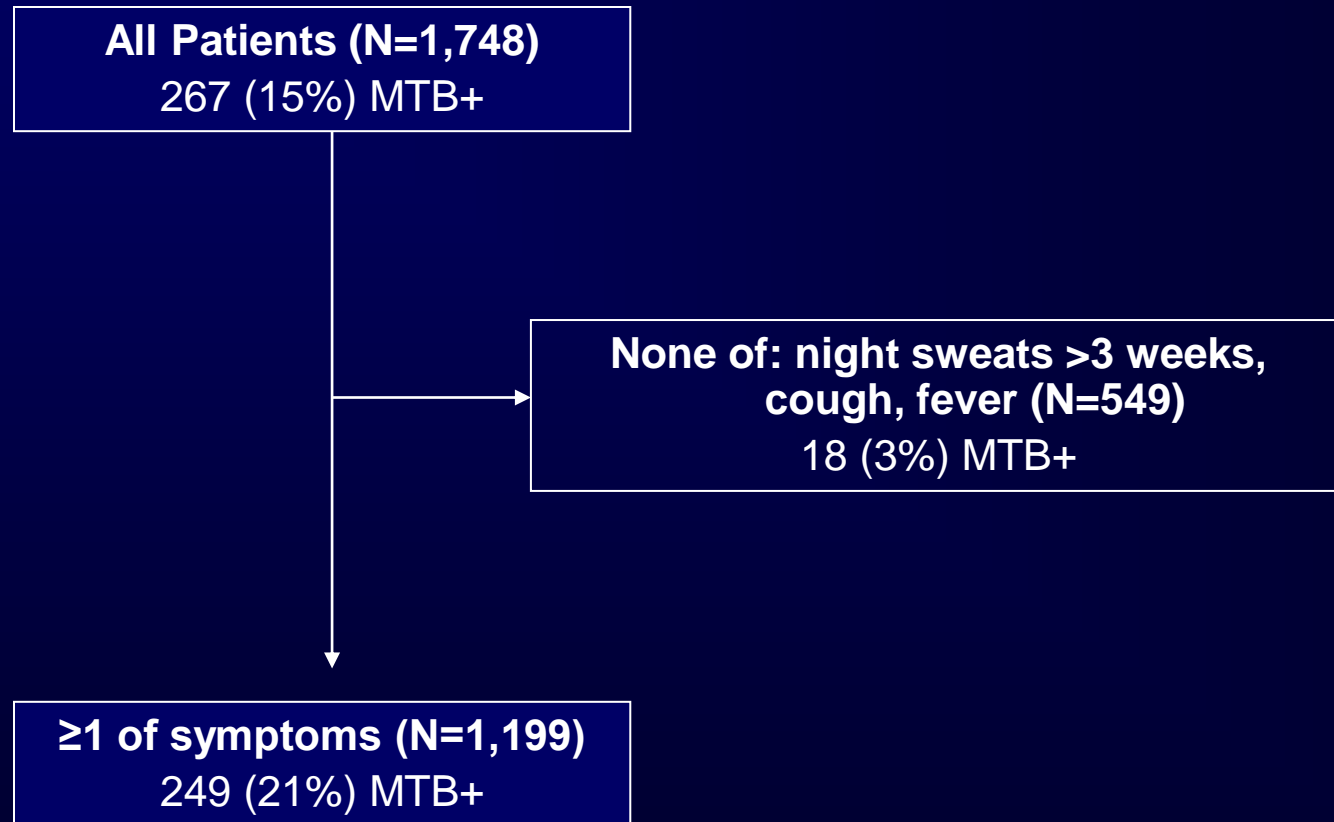

# Summary results: TB screening

- Chronic cough, or any other single symptom, is not sufficiently sensitive for TB screening in people with HIV
- Combination of symptoms achieves sensitivity >90%
  - Much better than standard methods
  - Achieving 100% not feasible

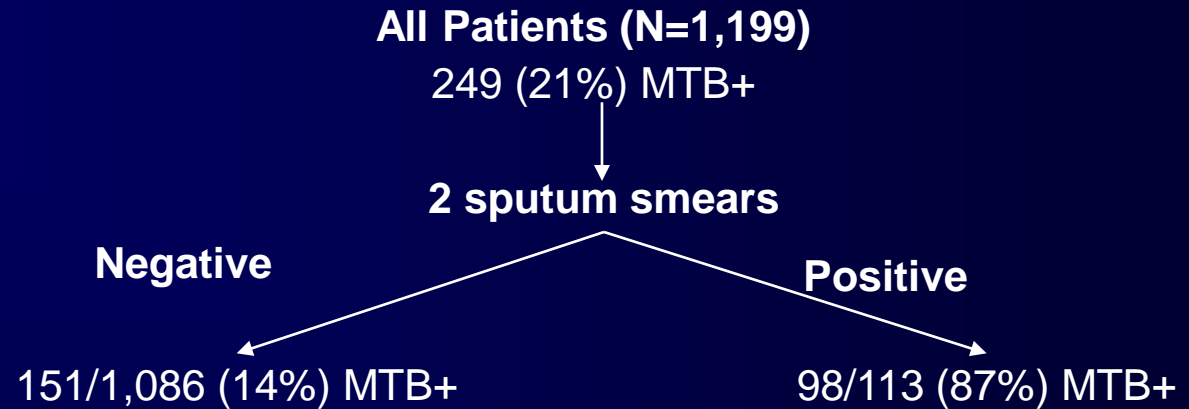

# Some candidate combinations

| Rule                                                                     | Sens (%) | Spec (%) |
|--------------------------------------------------------------------------|----------|----------|
| <b>1 of 2 rules</b>                                                      |          |          |
| Cough, fever                                                             | 91       | 37       |
| Cough in past 24 hours, fever                                            | 88       | 44       |
| <b>1 of 3 rules</b>                                                      |          |          |
| Cough, fever, drenching night sweats $\geq 3$ weeks                      | 93       | 36       |
| Cough, drenching night sweats, loss of appetite                          | 93       | 35       |
| Cough in the past 24 hours, fever, drenching night sweats $\geq 3$ weeks | 90       | 43       |

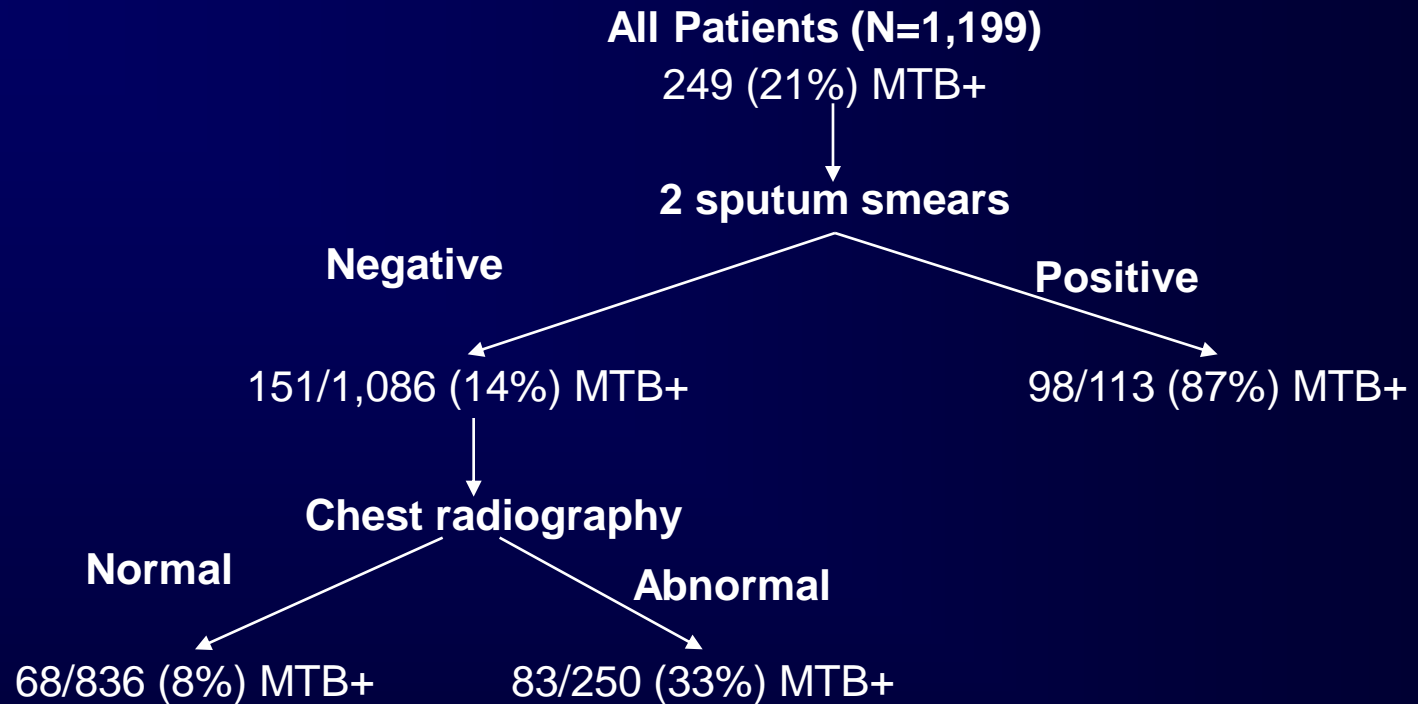

# Application of candidate approach to screening

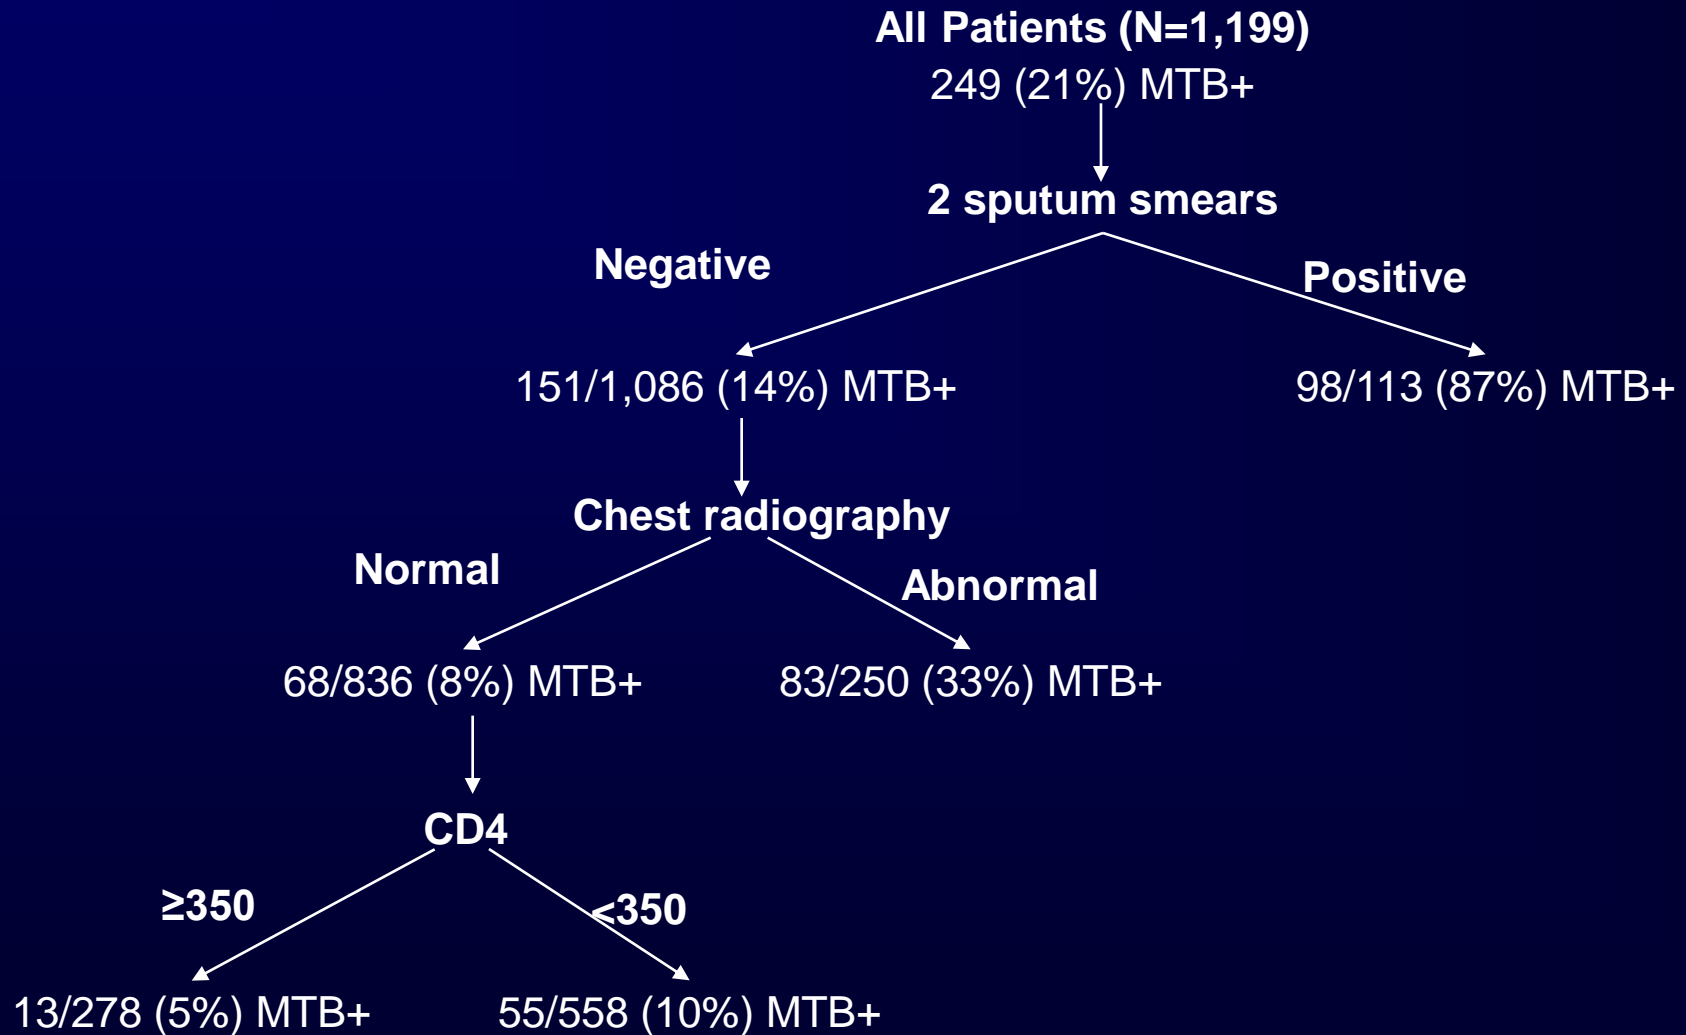

# Diagnostic Algorithm

# Diagnostic Algorithm

# Diagnostic Algorithm

# Diagnostic Algorithm

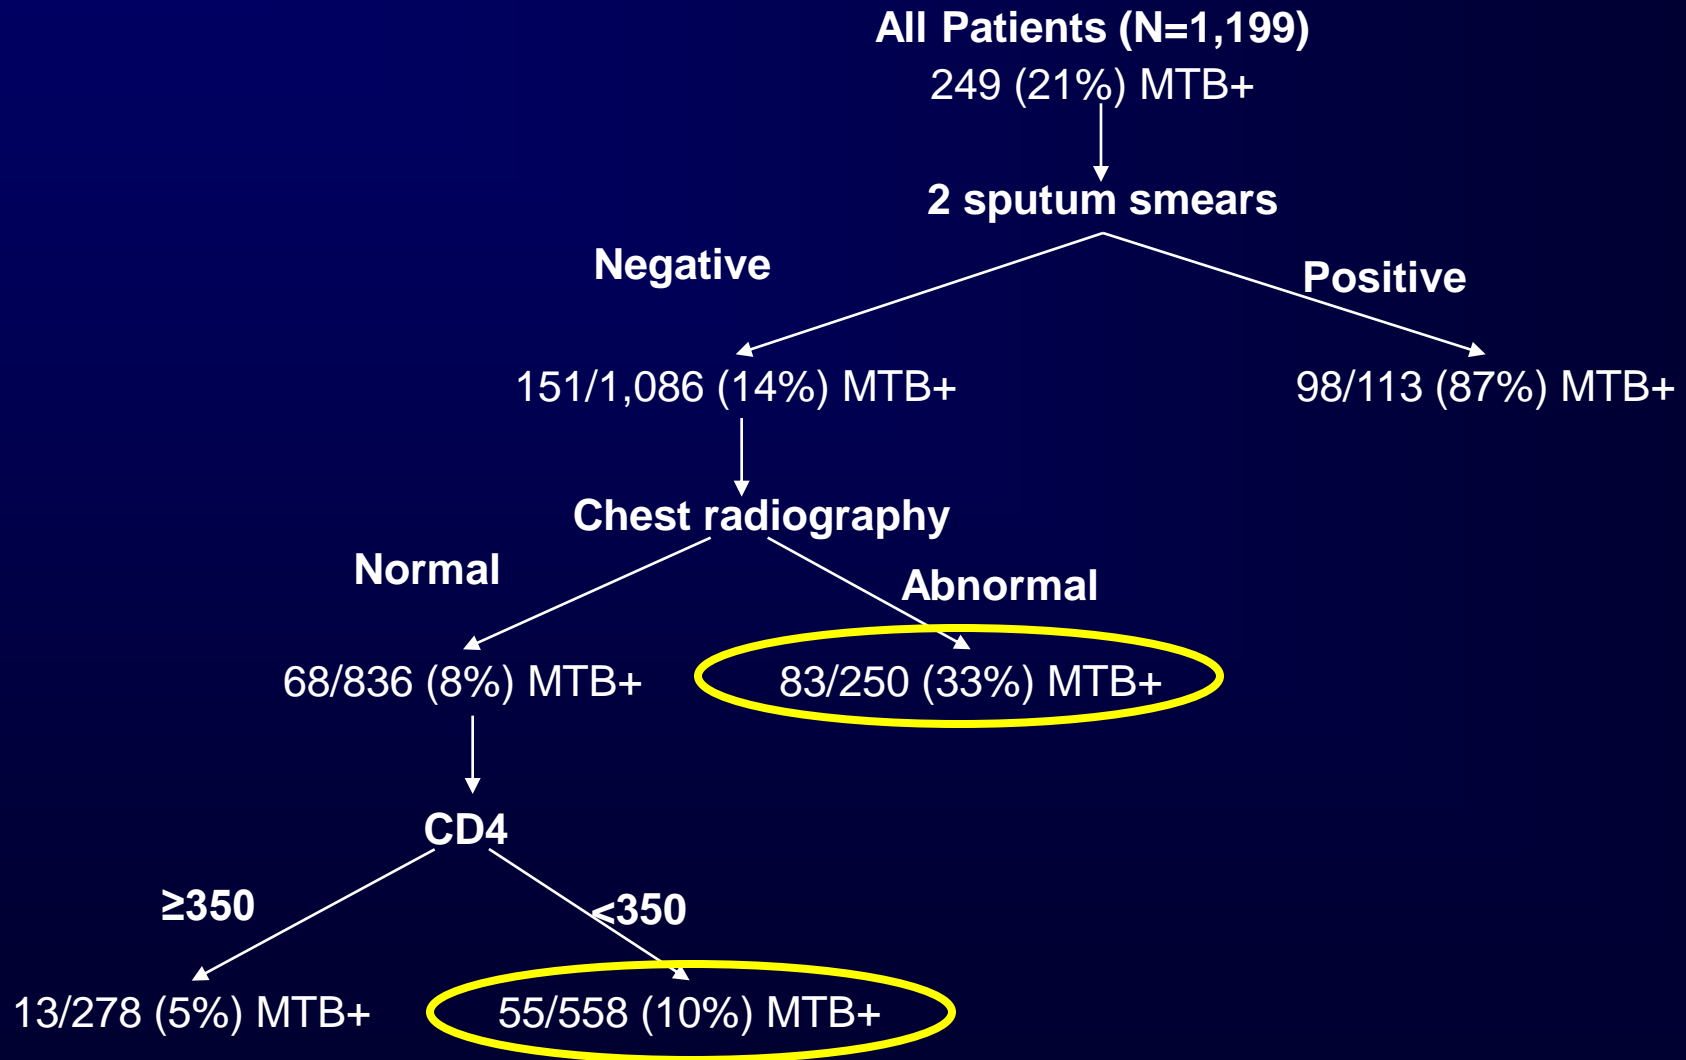

# Diagnostic Algorithm

# Diagnostic Algorithm

# Comparison to other commonly used approaches

- We compared this algorithm to other commonly used approaches
  - WHO diagnosis of smear-negative TB, recommends initial screening for cough  $>2$  or 3 weeks
  - Alternative: Sputum smears and chest radiography for every patient, TB ruled out if both negative
- Evaluated number of false negatives, resource utilization, and characteristics of false negatives

# Comparison of approaches (N=1,748 patients)

|                              | WHO   | Smear/x<br>-ray | Algorithm |
|------------------------------|-------|-----------------|-----------|
| # excluded by symptom screen | 1,393 | N/A             | 549       |
| # patients needing smears    | 355   | 1,748           | 1,199     |
| # x-rays                     | 300   | 1,748           | 1,086     |
| # needing TB culture         | 300   | N/A             | 808       |
| # False negatives            | ≥179  | 75              | 31        |
| False negatives, median CD4  | 398   | 146             | 112       |

# Conclusions: Screening

- **Cough  $\geq 2$  or 3 weeks insensitive (22-33% sensitivity), should not be used alone as initial screening**
  - WHO algorithm for diagnosing smear-negative TB should be modified
- **No other single symptom sufficiently sensitive**
- **Combination of symptoms (1 of 3)**
  - Can be highly sensitive
  - Example – any 1 of: night sweats  $\geq 3$  weeks, fever, cough
  - Simple, performs as well as or better than other approaches that we evaluated

# Conclusions: Diagnosis

- **Best approach based on available data**
  - **Symptom screen, then**
  - **Sputum smears, then chest radiograph, then CD4 testing**
- **It is ok if some steps occur at the same time, then this can be used as a decision tree**
- **Decreases smear and chest radiograph utilization**
- **Culture required for at least ~45% of people with HIV in order to diagnose TB**
- **Liquid culture much more sensitive than solid culture (data not shown)**

# Some next steps

## Cambodia

- Cambodian Revised TB/HIV Framework/SOP drafted
- New guidelines to be implemented in next year
- Evaluation of new algorithm in field setting
  - Use new algorithm in selected sites; include IPT track for those eligible
  - Evaluate performance, acceptability, resources

## International

- Meta-analysis including this and other studies → expert meeting Oct 2009 to revise WHO guidelines for ICF in PLHA
- Enhanced evaluation of algorithm (Thailand, Viet Nam, Kenya)
- Cost-effectiveness analysis (Thailand)

# Summary

- **Important new research findings on how to screen for TB among PLHA should reduce deaths**
- **Ongoing evaluation required to confirm algorithm performance**
- **High-quality operational research can address important programmatic questions and provide practical recommendations**
- **Requires:**
  - **Well-defined questions**
  - **Engagement of programme managers at all stages of planning, implementation, analysis (partnerships!)**
  - **Effective, rapid sharing of findings**
